

The three common practices that I violate in my "[badcalculator.py](#)" file are, KISS, YAGNI, Documentation, and naming practices.

- With kiss my code was not simple at all. I added if else statements that weren't necessary, added unnecessary global variables, and overcomplicated and doubled the amount of calculations that I needed.
- With YAGNI, I added variables that weren't used, if else statements that were pointless, and a variable that the user didn't need to input.
- With documentation I didn't add any at all, making the code over all more complicated to understand.
- Lastly with naming practices I made the variable name either too long and complicated, not using camel case or underscores to separate words, some variable names were too short not making it clear what they were, and the name of the file again was too long and complicated, making it hard to read.
